

# Course: PHP from scratch

by Sergey Podgornyy

PHP basics

# About me

**Sergey Podgornyy**

Full-Stack Web Developer

and

# Overview

- How PHP works? What is php.ini?
- PHP tags and comments
- Error reporting / `error_reporting` in php.ini
- Variables
- Output data: `echo`, `print`, `HEREDOC`, `NOWDOC`
- Magic constants
- Operators in PHP
- Data types
- Comparison operators
- Logic operators
- Conditional Statements

# What is PHP?

## *PHP: Hypertext Preprocessor*

PHP is a **server scripting language**, and a powerful tool for making dynamic and interactive Web pages

PHP is a widely-used, free, and efficient alternative to competitors such as Microsoft's ASP

# The configuration file

The configuration file (`php.ini`) is read when PHP starts up. For the server module versions of PHP, this happens **only once when the web server is started**. For the CGI and CLI versions, it happens on every invocation

# Error reporting

`error_reporting` — sets which PHP errors are reported

PHP 5.3 or later, the default value is `E_ALL & ~E_NOTICE & ~E_STRICT & ~E_DEPRECATED`

This setting does not show `E_NOTICE`, `E_STRICT` and `E_DEPRECATED` level errors. You may want to show them during development

# PHP Syntax

- A PHP script can be placed anywhere in the document
- The default file extension for PHP files is ".php"
  - A PHP script starts with `<?php` and ends with `?>`

```
1 <?php      ?>
```

```
3 <?        ?>
```

available if short\_open\_tag in php.ini

```
5 <?=      ?>
```

available if short\_open\_tag in php.ini

# Comments

- Let others understand what you are doing
  - Remind yourself of what you did

PHP supports several ways of commenting:

```
1 <?php
2 // This is a single-line comment
3
4 # This is also a single-line comment
5
6 /*
7 This is a multiple-lines comment block
8 that spans over multiple
9 lines
10 */
11
12 // You can also use comments to leave out parts of a code line
13 $x = 5 /* + 15 */ + 5;
14
```

# Variables

Think of variables as containers for storing data.

Remember that PHP variable names are case-sensitive!

- A variable starts with the \$ sign, followed by the name of the variable
- A variable name must **start with** a letter or the underscore character
- A variable name **cannot start** with a number
- A variable name **can only contain** alpha-numeric characters and underscores (A-z, 0-9, and \_)
- Variable names are **case-sensitive** (\$age and \$AGE are two different variables)

# echo and print statements

echo and print are more or less the same.  
They are both used to **output data** to the screen

*The differences are small:*

echo has **no return value**  
while print has a **return value of 1** so it can be  
used in expressions

# echo and print statements

```
1 <?php
2
3 // echo examples goes here
4 echo "Hello world!<br>";
5 echo "This ", "string ", "was ", "made ", "with multiple parameters.";
6
7 $txt1 = "Learn PHP";
8 echo "<h2>$txt1</h2>";
9
10 $x = 5; $y = 4;
11 echo $x + $y;
12
13 // print examples goes here
14 print "Hello world!<br>";
15 print "I'm about to learn PHP!";
16
17 $txt1 = "PHPAcademy";
18 print "Study PHP at $txt1<br>";
19
20 $x = 5; $y = 4;
21 print $x + $y;
22
```

# HEREDOC & NOWDOC

```
1  <?php
2
3  $name = 'MyName';
4
5  // HEREDOC example
6  echo <<<EOT
7  My name is "$name". I am printing some Foo.
8  This should print a capital 'A': \x41
9  EOT;
10
11 // NOWDOC example (since PHP 5.3.0)
12 echo <<<'EOT'
13 My name is "$name". I am printing some Foo.
14 This should not print a capital 'A': \x41
15 EOT;
16
```

# Predefined magic constants

A few "magical" PHP constants

Name	Description
<code>__LINE__</code>	The current line number of the file.
<code>__FILE__</code>	The full path and filename of the file with symlinks resolved. If used inside an include, the name of the included file is returned.
<code>__DIR__</code>	The directory of the file. If used inside an include, the directory of the included file is returned. This is equivalent to <code>dirname(__FILE__)</code> . This directory name does not have a trailing slash unless it is the root directory.
<code>__FUNCTION__</code>	The function name.
<code>__CLASS__</code>	The class name. The class name includes the namespace it was declared in (e.g. <code>Foo\Bar</code> ). Note that as of PHP 5.4 <code>__CLASS__</code> works also in traits. When used in a trait method, <code>__CLASS__</code> is the name of the class the trait is used in.
<code>__TRAIT__</code>	The trait name. The trait name includes the namespace it was declared in (e.g. <code>Foo\Bar</code> ).
<code>__METHOD__</code>	The class method name.
<code>__NAMESPACE__</code>	The name of the current namespace.

# Data Types

PHP supports the following data types:

- String
- Integer
- Float (floating point numbers - also called double)
- Boolean
- Array
- Object
- NULL
- Resource

# Data Types

**isset** — Determine if a variable is set and is  
not NULL

**empty** — Determine whether a variable is empty

**gettype** — Get the type of a variable

Returns the type of the PHP variable var. For type checking, use **is\_\*** functions

# Data Types

- **is\_array()** - Finds whether a variable is an array
- **is\_bool()** - Finds out whether a variable is a boolean
- **is\_callable()** - Verify that the contents of a variable can be called as a function
- **is\_float()** - Finds whether the type of a variable is float
- **is\_int()** - Find whether the type of a variable is integer
- **is\_null()** - Finds whether a variable is NULL
- **is\_numeric()** - Finds whether a variable is a number or a numeric string
- **is\_object()** - Finds whether a variable is an object
- **is\_resource()** - Finds whether a variable is a resource
- **is\_scalar()** - Finds whether a variable is a scalar
- **is\_string()** - Find whether the type of a variable is string

# Operators

PHP divides the operators  
in the following groups:

- Arithmetic operators
- Assignment operators
- Comparison operators
- Increment/Decrement operators
- Logical operators
- String operators
- Array operators

# Arithmetic Operators

Operator	Name	Example	Result
+	Addition	$\$x + \$y$	Sum of $\$x$ and $\$y$
-	Subtraction	$\$x - \$y$	Difference of $\$x$ and $\$y$
*	Multiplication	$\$x * \$y$	Product of $\$x$ and $\$y$
/	Division	$\$x / \$y$	Quotient of $\$x$ and $\$y$
%	Modulus	$\$x \% \$y$	Remainder of $\$x$ divided by $\$y$
**	Exponentiation	$\$x ** \$y$	Result of raising $\$x$ to the $\$y$ 'th power (Introduced in PHP 5.6)

# Assignment Operators

Assignment	Same as...	Description
<code>x = y</code>	<code>x = y</code>	The left operand gets set to the value of the expression on the right
<code>x += y</code>	<code>x = x + y</code>	Addition
<code>x -= y</code>	<code>x = x - y</code>	Subtraction
<code>x *= y</code>	<code>x = x * y</code>	Multiplication
<code>x /= y</code>	<code>x = x / y</code>	Division
<code>x %= y</code>	<code>x = x % y</code>	Modulus

# Comparison Operators

Operator	Name	Example	Result
==	Equal	<code>\$x == \$y</code>	Returns true if <code>\$x</code> is equal to <code>\$y</code>
===	Identical	<code>\$x === \$y</code>	Returns true if <code>\$x</code> is equal to <code>\$y</code> , and they are of the same type
!=	Not equal	<code>\$x != \$y</code>	Returns true if <code>\$x</code> is not equal to <code>\$y</code>
<>	Not equal	<code>\$x &lt;&gt; \$y</code>	Returns true if <code>\$x</code> is not equal to <code>\$y</code>
!==	Not identical	<code>\$x !== \$y</code>	Returns true if <code>\$x</code> is not equal to <code>\$y</code> , or they are not of the same type
>	Greater than	<code>\$x &gt; \$y</code>	Returns true if <code>\$x</code> is greater than <code>\$y</code>
<	Less than	<code>\$x &lt; \$y</code>	Returns true if <code>\$x</code> is less than <code>\$y</code>
>=	Greater than or equal to	<code>\$x &gt;= \$y</code>	Returns true if <code>\$x</code> is greater than or equal to <code>\$y</code>
<=	Less than or equal to	<code>\$x &lt;= \$y</code>	Returns true if <code>\$x</code> is less than or equal to <code>\$y</code>

# Increment / Decrement Operators

Operator	Name	Description
++\$x	Pre-increment	Increments \$x by one, then returns \$x
\$x++	Post-increment	Returns \$x, then increments \$x by one
--\$x	Pre-decrement	Decrements \$x by one, then returns \$x
\$x--	Post-decrement	Returns \$x, then decrements \$x by one

```
1 <?php
2
3 $value = 0;
4
5 echo $value++; // return 0
6 echo $value;   // return 1
7 echo ++$value; // return 2
8
```

# Logical Operators

Operator	Name	Example	Result
and	And	<code>\$x and \$y</code>	True if both <code>\$x</code> and <code>\$y</code> are true
or	Or	<code>\$x or \$y</code>	True if either <code>\$x</code> or <code>\$y</code> is true
xor	Xor	<code>\$x xor \$y</code>	True if either <code>\$x</code> or <code>\$y</code> is true, but not both
<code>&amp;&amp;</code>	And	<code>\$x &amp;&amp; \$y</code>	True if both <code>\$x</code> and <code>\$y</code> are true
<code>  </code>	Or	<code>\$x    \$y</code>	True if either <code>\$x</code> or <code>\$y</code> is true
<code>!</code>	Not	<code>!\$x</code>	True if <code>\$x</code> is not true

# String Operators

Operator	Name	Example	Result
.	Concatenation	\$txt1 . \$txt2	Concatenation of \$txt1 and \$txt2
.=	Concatenation assignment	\$txt1 .= \$txt2	Appends \$txt2 to \$txt1

```
1 <?php
2
3 $txt1 = "Hello";
4 $txt2 = " world!";
5 echo $txt1 . $txt2;
6
7 $txt1 .= $txt2;
8 echo $txt1;
9
```

# Conditional Statements

In PHP we have the following conditional statements:

- **if** statement - executes some code if one condition is true
- **if...else** statement - executes some code if a condition is true and another code if that condition is false
- **if...elseif....else** statement - executes different codes for more than two conditions
- **switch** statement - selects one of many blocks of code to be executed
